# First Order String Theory and the Kodaira-Spencer Equations. I

O. Gamayun[§], A. S. Losev[¶], A. Marshakov[‖]

We consider first-order bosonic string theory, perturbed by the primary operator, corresponding to deformation of the target-space complex structure. We compute the effective action in this theory and find that its consistency with the world-sheet conformal invariance requires necessarily the Kodaira-Spencer equations to be satisfied by target-space Beltrami differentials. We discuss the symmetries of the theory and its reformulation in terms of the vielbein background fields.

## 1 Introduction

The formulation of string theory in non-trivial background is a long-standing nontrivial problem (see e.g. [1, 2]). The most traditional approach [3, 4] is based almost totally on studying the two-dimensional sigma-models, where many issues directly concerning the basic principles of string theory are hidden behind the serious technical problems of computations in nonlinear interacting theories. Even the heart of perturbative string theory - the concept of two-dimensional conformal invariance - is not directly seen within this approach, since the theory is conformally-invariant only on mass shell, which basically forbids to consider the most part of the interesting deformations of the target-space background.

In order to try to avoid at least some of these complications, it has been proposed in [5] to study the simplest possible string model - the first-order string theory with the “bare action” of the bosonic first-order free conformal field theory

$$S_0 = \frac{1}{2\pi\alpha'}\int_\Sigma d^2z(p_i\bar\partial X^i + p_{\bar i}\partial X^{\bar i}) \tag{1}$$

which is independent of the target-space metric and requires only some (local) choice of the complex structure. Analogy with the Hamiltonian formalism in the theory of particle suggests that (1) corresponds at least naively to a background with the singular target-space metric (and the singular Kalb-Ramond $B$-field [5]). The world-sheet fields $\{X^\mu\} = \{(X^i, X^{\bar i})\}$, $\{p_i\}$ and $\{p_{\bar i}\}$ (with $\mu = 1,\dots,D$; $i,\bar i = 1,\dots,D/2$) are sections of $H^0(\Sigma)$, $H^{(1,0)}(\Sigma)$ and $H^{(0,1)}(\Sigma)$

correspondingly, being holomorphic (or anti-holomorphic) on the equations of motion. The only nontrivial operator product expansions (OPE) for the theory (1) are

$$p_i(z)X^j(z') = \frac{\alpha'\delta_i^j}{z-z'} + \text{regular terms} \tag{2}$$

together with their complex conjugated.

The free field theory action (1) can be naturally perturbed by the operators

$$V_g = \frac{1}{2\pi\alpha'}\int_\Sigma O_g = \frac{1}{2\pi\alpha'}\int_\Sigma d^2z g^{i\bar{j}} p_i p_{\bar{j}} \tag{3}$$

with the $X$-dependent "coefficient functions" or target-space fields $g^{i\bar{j}} = g^{i\bar{j}}(X)$, as well as

$$\begin{aligned} V_\mu &= \frac{1}{2\pi\alpha'}\int_\Sigma O_\mu = \frac{1}{2\pi\alpha'}\int_\Sigma d^2z \mu^j_{\bar{i}} \bar{\partial} X^{\bar{i}} p_j \\ V_{\bar{\mu}} &= \frac{1}{2\pi\alpha'}\int_\Sigma O_{\bar{\mu}} = \frac{1}{2\pi\alpha'}\int_\Sigma d^2z \bar{\mu}^{\bar{j}}_i \partial X^i p_{\bar{j}} \end{aligned} \tag{4}$$

where $\mu^j_{\bar{i}} = \mu^j_{\bar{i}}(X)$ (together with its complex conjugated $\bar{\mu}^{\bar{i}}_j = \bar{\mu}^{\bar{i}}_j(X)$), and

$$V_b = \frac{1}{2\pi\alpha'}\int_\Sigma O_b = \frac{1}{2\pi\alpha'}\int_\Sigma d^2z b_{i\bar{j}} \partial X^i \bar{\partial} X^{\bar{j}} \tag{5}$$

where again $b_{i\bar{j}} = b_{i\bar{j}}(X)$. It is also often useful to define the "real" operator

$$\Phi(z,\bar{z}) = O_\mu(z,\bar{z}) + O_{\bar{\mu}}(z,\bar{z}) = \mu^j_{\bar{i}} \bar{\partial} X^{\bar{i}} p_j + \bar{\mu}^{\bar{j}}_i \partial X^i p_{\bar{j}} \tag{6}$$

In order for the operators (3),(4) and (6) to be well-defined as conformal primary operators, one has to impose the transversality conditions for the background fields

$$\begin{aligned} \partial_i g^{i\bar{j}} = 0, &\quad \partial_{\bar{j}} g^{i\bar{j}} = 0 \\ \partial_i \mu^i_{\bar{j}} = 0, &\quad \partial_{\bar{j}} \bar{\mu}^{\bar{j}}_i = 0 \end{aligned} \tag{7}$$

which allow to get rid of the singularities, possibly arising from "internal" contractions in (3),(4) and (6) or, in different words, the higher-order poles in the operator-product expansions with the components of the stress-energy tensor $T \sim p_i\partial X^i$ and $\bar{T} \sim p_{\bar{i}}\bar{\partial}X^{\bar{i}}$ in the bare theory (1).

The operators (3)-(5) (or (6)) are the only possible marginal $(\Delta, \bar{\Delta}) = (1,1)$ primary operators in the first-order theory (1). In addition, one can also introduce the holomorphic $(1,0)$-currents

$$\begin{aligned} j_v = p_i v^i(X), &\quad \partial_i v^i = 0 \\ j_\omega = \omega_i(X)\partial X^i & \end{aligned} \tag{8}$$

(and their anti-holomorphic $(0,1)$-conjugates), which generate the holomorphic change of coordinates and gauge transformations (their anomalous operator algebra has been studied in [6, 7, 5, 8]). The non-holomorphic operators, similar to (8), can also arise when studying generic non-holomorphic symmetries of the perturbed action, and these symmetries will be partly considered below.

We are going to study the conditions, when the operators (3)-(5) become exactly marginal or can be raised up to the exponent and added to the free action (1). In other words, this is equivalent to vanishing of their beta-functions in the perturbed theory [1, 9]. The quadratic (in background fields) contributions to these beta-functions are given by the structure constants of the OPE's of the primary operators (3)-(5), whose vanishing leads, for example, to the nonlinear equation

$$g^{i\bar j}\partial_i\partial_{\bar j}g^{k\bar l} - \partial_i g^{k\bar j}\partial_{\bar j}g^{i\bar l} = 0 \tag{9}$$

for the functions $g^{i\bar j}(X)$, shown to be a direct analog of the Einstein equations for the physical fields $G$, $B$ and $\Phi$ (the target-space metric, the Kalb-Ramond antisymmetric two-form and the dilaton), related with the background fields $g$, $\mu$, $\bar\mu$ and $b$ from (3), (4) and (5) by a nontrivial transformation [5]. In the present paper we would like to concentrate mostly on the background equations of motion for the target-space "Beltrami" fields[1] $\mu = dX^{\bar j}\mu^i_{\bar j}\frac{\partial}{\partial X^i}$ and $\bar\mu = dX^i\bar\mu^{\bar j}_i\frac{\partial}{\partial X^{\bar j}}$, keeping the other fields to be shut down for a while, or playing maximally a role of a "spectator" or "probe" operators. In such case the vertex operators (4) and (6) can be obviously considered as deforming the complex structure of the original bare theory (1), and from generic target-space symmetry reasons one would expect that the corresponding fields should satisfy the Kodaira-Spencer equations [12]

$$\begin{aligned} N^i_{\bar k\bar j} &\equiv \partial_{[\bar k}\mu^i_{\bar j]} - \mu^l_{[\bar k}\partial_l\mu^i_{\bar j]} = 0 \\ \bar N^{\bar j}_{ik} &\equiv \partial_{[i}\bar\mu^{\bar j}_{k]} - \bar\mu^{\bar l}_{[i}\partial_{\bar l}\bar\mu^{\bar j}_{k]} = 0 \end{aligned} \tag{10}$$

which have an obvious sense of vanishing of the Nijenhuis tensor or curvatures for the gauge fields $\mu = dX^{\bar j}\mu^i_{\bar j}\frac{\partial}{\partial X^i}$ and $\bar\mu = dX^i\bar\mu^{\bar j}_i\frac{\partial}{\partial X^{\bar j}}$ with the values in Lie algebra of the vector fields in tangent bundle to the target manifold (see [13] for brief description of Kodaira-Spencer theory and their important applications for topological strings). Below we are going to derive these equations directly from the consistency of perturbed first-order conformal field theory.

## 2 Background field expansion

The most common analysis of the beta-functions follows from studying logarithmic divergences in the effective action, coming from its one-loop computation (see various issues of this procedure e.g. in [3, 2, 14]). Consider the first-order theory with the action $S = S_0 + \int_\Sigma \Phi$ and decompose the would-sheet fields into the fast and slow (or quantum and classical) parts $X \to X_{\rm cl} + \sqrt{\alpha'}X$ and $p \to p^{\rm cl} + \sqrt{\alpha'}p$.

Expanding the Lagrangian up to the second order one gets

$$\mathcal{L} = \mathcal{L}_0 + \Phi = \mathcal{L}_{\rm cl} + \alpha'\left(p_i\bar\partial\tilde X^i + p_i\bar\partial X^{\bar j}_{\rm cl}\partial_k\mu^i_{\bar j}(X_{\rm cl})\tilde X^k + p_i\bar\partial X^{\bar j}_{\rm cl}N^i_{\bar k\bar j}(X_{\rm cl})X^{\bar k} + c.c.\right) + o(\alpha') \tag{11}$$

where

$$\tilde X^i = X^i + \mu^i_{\bar k}(X_{\rm cl})X^{\bar k} \tag{12}$$

---

[1] These fields in the context of Lagrangian field theory were discussed already in [10], the Beltrami parametrization of the world-sheet geometry in string theory was discussed e.g. in [11].

and the Kodaira-Spencer term $N^{i}_{\bar k \bar j}$ has been already defined in (10). The change of quantum co-ordinates (12) is an obvious transformation of the target-space complex polarization $\{X^i, X^{\bar i}\} \to \{\tilde X^i, \tilde X^{\bar i}\}$, caused by expansion around the classical background $X_{\rm cl}$ instead of the zero background, originally taken if directly dealing with the bare action (1).

The linear in fluctuations terms disappear from (11) due to the equations of motion

$$\bar\partial X^i_{\rm cl} + \mu^i_{\bar j}(X_{\rm cl})\partial X^{\bar j}_{\rm cl} = 0 \tag{13}$$

together with its complex conjugated, and

$$\left(\bar\nabla p^{\rm cl}\right)_k + \bar\mu^{\bar i}_k(X_{\rm cl})\left(\nabla p^{\rm cl}\right)_{\bar i} = p^{\rm cl}_{\bar i}\partial X^j_{\rm cl}\bar N^{\bar i}_{kj}(X_{\rm cl}) \tag{14}$$

with

$$\left(\bar\nabla p^{\rm cl}\right)_k = \bar\partial p^{\rm cl}_k - \partial_k\mu^i_{\bar j}(X_{\rm cl})\bar\partial X^{\bar j}_{\rm cl} p^{\rm cl}_i \tag{15}$$

Note, that the combination (10) arises already in the r.h.s. of the *classical* equations for momenta, which turn into $\left(\bar\nabla p^{\rm cl}\right)_k = 0$ together with its complex conjugated for the background fields $\mu(X_{\rm cl})$ obeying the Kodaira-Spencer equations.

After the change of variables, inverse to (12), one gets for the "old co-ordinates"

$$\begin{aligned} X^{\bar k} &= \left((1-\bar\mu\mu(X_{\rm cl}))^{-1}\right)^{\bar k}_{\bar l}\tilde X^{\bar l} - \bar\mu^{\bar k}_s(X_{\rm cl})\left((1-\mu\bar\mu(X_{\rm cl}))^{-1}\right)^s_l\tilde X^l = \\ &= \bar M^{\bar k}_{\bar l}(X_{\rm cl})\tilde X^{\bar l} - \bar\mu^{\bar k}_s(X_{\rm cl})M^s_l(X_{\rm cl})\tilde X^l \end{aligned} \tag{16}$$

where

$$M^i_j = \left(\delta^i_j - (\mu\bar\mu)^i_j\right)^{-1} \tag{17}$$

(together with the corresponding complex conjugated formulas), and the Lagrangian (11) acquires the form

$$\mathcal{L} = \mathcal{L}_0 + \Phi = \mathcal{L}_{\rm cl} + \alpha'\left(p_i\bar\partial\tilde X^i + p_iU^i_{\bar j}\tilde X^{\bar j} + p_iW^i_j\tilde X^j + c.c\right) + o(\alpha') \tag{18}$$

where

$$U^i_{\bar j} = N^i_{\bar k\bar l}\bar M^{\bar k}_{\bar j}(X_{\rm cl})\bar\partial X^{\bar l}_{\rm cl} \tag{19}$$

and

$$W^i_j = \bar\partial X^{\bar j}_{\rm cl}\left(\partial_j\mu^i_{\bar j}(X_{\rm cl}) - N^i_{\bar k\bar j}\bar\mu^{\bar k}_s M^s_j(X_{\rm cl})\right) \tag{20}$$

(together with their complex conjugated) are two dependent on external fields $X_{\rm cl}$ set of vertices, to be treated as perturbation of the free field theory $\tilde{\mathcal{L}}_0 = p_i\bar\partial\tilde X^i + c.c.$ with the propagators

$$\begin{aligned} \langle p_i(z)\tilde X^j(z')\rangle &= \frac{\delta^j_i}{z-z'} = \delta^j_i\int\frac{d^2q}{(2\pi)^2}\frac{e^{i\mathbf{q}(\mathbf{z}-\mathbf{z}')}}{\bar q} \\ \langle p_{\bar i}(z)\tilde X^{\bar j}(z')\rangle &= \frac{\delta^{\bar j}_{\bar i}}{\bar z-\bar z'} = \delta^{\bar j}_{\bar i}\int\frac{d^2q}{(2\pi)^2}\frac{e^{i\mathbf{q}(\mathbf{z}-\mathbf{z}')}}{q} \end{aligned} \tag{21}$$

An important observation is that both vertices (19) and (20) do *not* depend on the momenta of quantum fields $X$ and $p$. Therefore, the only logarithmically divergent contribution to the

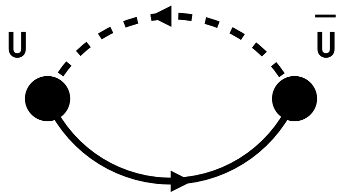

Figure 1: The only 2-vertex 1-loop diagram which diverges logarithmically. Black and dash lines denote the holomorphic and anti-holomorphic propagators from (21).

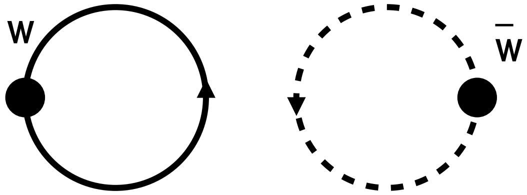

Figure 2: The 1-loop tadpole diagrams which give rise naively to a linear divergences. Black and dash lines again denote the holomorphic and anti-holomorphic propagators from (21).

effective action comes from the paring of $U^i_{\bar{j}}$ and $\bar{U}^{\bar{j}}_i$ vertices or from the diagram depicted at fig. 1, which gives the contribution

$$\Gamma^{\rm div} \sim \int d^2z\, \frac{U^i_{\bar{j}}(z)\bar{U}^{\bar{j}}_i(0)}{|z|^2} \sim U^i_{\bar{j}}\bar{U}^{\bar{j}}_i \int \frac{d^2q}{q\bar{q}} \tag{22}$$

The logarithmically divergent integrals in (22) can be just cut off, say by $|z| > \epsilon$, which leads to the renormalization of the operator of type (5)

$$\delta b_{i\bar{j}} \sim \log\epsilon \cdot B_{i\bar{j}} \tag{23}$$

where

$$\begin{aligned} B_{i\bar{j}} &= -N^l_{\bar{k}\bar{j}}\bar{N}^{\bar{l}}_{ki}M^k_l\bar{M}^{\bar{k}}_{\bar{l}} \equiv B^{(2)}_{i\bar{j}} + B^{(3)}_{i\bar{j}} + \bar{B}^{(3)}_{i\bar{j}} + O(\mu^4) = \\ &= -\partial_{[k}\bar{\mu}^{\bar{k}}_{i]}\partial_{[\bar{k}}\mu^k_{\bar{j}]} + \partial_{[k}\bar{\mu}^{\bar{k}}_{i]}\mu^l_{[\bar{k}}\partial_l\mu^i_{\bar{j}]} + \partial_{[\bar{k}}\mu^k_{\bar{j}]}\bar{\mu}^{\bar{l}}_{[k}\partial_{\bar{l}}\bar{\mu}^{\bar{k}}_{i]} + O(\mu^4) \end{aligned} \tag{24}$$

obviously vanishing on the solutions to (10). The Jacobian of transformation (12) which changes the measure in the path integral is derivative independent, and therefore does not affect the result of computation of the one-loop diagram in the theory (18). Actually, this result is even exact in all orders in $\alpha'$, since any vertex, obtained by the $\alpha'$ expansion (11), has a single $p$ ($\bar{p}$) together with many $\tilde{X}$ ($\bar{\tilde{X}}$) legs, so that one cannot in principle construct a diagram with more than one loops.

Finally in this section let us point out, that vertices (20) could be perhaps neglected, if the current $j_v$ from (8) is not anomalous: they can produce only the linearly divergent tadpole diagrams (see fig. 2), where the divergency is killed by the angle integration. However, since $\bar{\partial}\langle j_v\rangle = \frac{1}{2\pi}R^{(2)}\partial_i v^i$, the presence of vertices (20) in the Lagrangian leads to creation of the terms

$$W^i_j\langle p_i\tilde{X}^j\rangle \sim \bar{\partial}X^{\bar{j}}_{\rm cl}N^i_{\bar{k}\bar{j}}\bar{\mu}^{\bar{k}}_sM^s_j(X_{\rm cl}) = \bar{\partial}X^{\bar{j}}_{\rm cl}N^i_{\bar{k}\bar{j}}\bar{\mu}^{\bar{k}}_i(X_{\rm cl}) + O(\mu^4) \tag{25}$$

We shall discuss in the second part of this paper [15], that extra terms like (25) are related to the higher singularities in the operator product expansions and can give rise to extra singularities in the correlation functions.

## 3 Symmetries

The bare action (1) is invariant under the holomorphic change of variables

$$\begin{aligned} X^i &\to X^i - v^i(X) \\ p_i &\to p_i + \partial_i v^k(X) p_k \end{aligned} \tag{26}$$

generated by the first current $j_v$ from (8), together with their complex conjugated. In order to study the general co-ordinate invariance of the theory one needs to switch on all background fields (3), (4) or (6), and (5). The general co-ordinate transformations of the fundamental variables of the first-order theory should be then supplemented by the transformations of the background fields.

The perturbed action

$$\begin{gathered} S = S_0 + \frac{1}{2\pi\alpha'}\int d^2z\,(O_g + O_\mu + O_{\bar\mu} + O_b) = \\ = \frac{1}{2\pi\alpha'}\int d^2z \left(p_i\bar\partial X^i + p_i\mu^i_{\bar j}\bar\partial X^{\bar j} + c.c.\right) + \frac{1}{2\pi\alpha'}\int d^2z \left(g^{i\bar j}p_ip_{\bar j} + b_{i\bar j}\partial X^i\bar\partial X^{\bar j}\right) \end{gathered} \tag{27}$$

is invariant already under the transformation of co-ordinates

$$X^i \to X^i - v^i(X,\overline{X}), \qquad X^{\bar j} \to X^{\bar j} - v^{\bar j}(X,\overline{X}) \tag{28}$$

where the momenta transform already in the background-field dependent way

$$p_i \to p_i + p_k(\partial_i v^k + \mu^k_{\bar k}\partial_i v^{\bar k}) + b_{j\bar k}\partial_i v^{\bar k}\partial X^j \tag{29}$$

together with the complex-conjugated formula. For the background fields themselves one gets

$$\begin{gathered} \mu^i_{\bar j} \to \mu^i_{\bar j} + \partial_{\bar j}v^i + v^k\partial_k\mu^i_{\bar j} + v^{\bar k}\partial_{\bar k}\mu^i_{\bar j} + \mu^i_{\bar k}\partial_{\bar j}v^{\bar k} - \mu^k_{\bar j}\partial_k v^i - \mu^i_{\bar k}\mu^k_{\bar j}\partial_k v^{\bar k} - g^{i\bar k}b_{l\bar j}\partial_{\bar k}v^l = \\ = \mu^i_{\bar j} + \partial_{\bar j}v^i + \{v,\mu\}^i_{\bar j} + v^{\bar k}\partial_{\bar k}\mu^i_{\bar j} + \mu^i_{\bar k}\left(\partial_{\bar j} - \mu^k_{\bar j}\partial_k\right)v^{\bar k} - g^{i\bar k}b_{l\bar j}\partial_{\bar k}v^l \end{gathered} \tag{30}$$

where

$$\{v,\mu\}^i_{\bar j} = v^k\partial_k\mu^i_{\bar j} - \mu^k_{\bar j}\partial_k v^i \tag{31}$$

is the Schouten bracket, or the analog of the commutator for the gauge connections with values in the Lie algebra of vector fields, and also

$$g^{i\bar j} \to g^{i\bar j} + v^k\partial_k g^{i\bar j} + v^{\bar k}\partial_{\bar k}g^{i\bar j} - g^{i\bar k}(\partial_{\bar k}v^{\bar j} + \bar\mu^{\bar j}_k\partial_{\bar k}v^k) - g^{k\bar j}(\partial_k v^i + \mu^i_{\bar k}\partial_k v^{\bar k}) \tag{32}$$

and

$$b_{i\bar j} \to b_{i\bar j} + v^k\partial_k b_{i\bar j} + v^{\bar k}\partial_{\bar k}b_{i\bar j} + b_{i\bar k}(\partial_{\bar j} - \mu^k_{\bar j}\partial_k)v^{\bar k} + b_{l\bar j}(\partial_i - \bar\mu^{\bar k}_i\partial_{\bar k})v^l \tag{33}$$

These transformations almost coincide with conventional Lie derivatives - they partially differ from naively expected target-space transformation law by replacing

$$
\begin{gathered}
\partial_k v^i \to \partial_k v^i + \mu^i_{\bar{k}} \partial_k v^{\bar{k}} \\
\partial_{\bar{j}} v^{\bar{k}} \to (\partial_{\bar{j}} - \mu^k_{\bar{j}} \partial_k) v^{\bar{k}} = \mathcal{D}_{\bar{j}} v^{\bar{k}}
\end{gathered}
\tag{34}
$$

or introducing, in the second line, the "long derivatives"

$$
\partial_{\bar{i}} \to \mathcal{D}_{\bar{i}} = \partial_{\bar{i}} - \mu^k_{\bar{i}} \partial_k, \qquad [\mathcal{D}_{\bar{i}}, \mathcal{D}_{\bar{j}}] = -N^k_{\bar{i}\bar{j}} \partial_k \tag{35}
$$

The sense of this replacement can be understood as follows: consider for simplicity constant background $\mu$-field, then when it is switched on the correct target-space holomorphic co-ordinate becomes $\hat{X}^i = X^i + \mu^i_{\bar{j}} X^{\bar{j}}$ (cf. also with (12)). Its infinitesimal variation $\hat{v}^i = v^i + \mu^i_{\bar{j}} v^{\bar{j}}$ under the transformation (28) stays in the first line of (34), while the corresponding $\bar{\partial}$-operator (35) (such that $\mathcal{D}_{\bar{j}} \hat{X}^i = 0$) appears in the second line of (34).

Transformation (30) (at vanishing $b$-field $b_{i\bar{j}} = 0$) induces the following transformation of the tensor $N^i_{\bar{k}\bar{j}} \equiv \partial_{[\bar{k}} \mu^i_{\bar{j}]} - \mu^l_{[\bar{k}} \partial_l \mu^i_{\bar{j}]}$

$$
\begin{gathered}
N^i_{\bar{s}\bar{j}} \to N^i_{\bar{s}\bar{j}} - (\partial_k v^i + \mu^i_{\bar{k}} \partial_k v^{\bar{k}}) N^k_{\bar{s}\bar{j}} + (\partial_{\bar{s}} v^{\bar{k}} - \mu^k_{\bar{s}} \partial_k v^{\bar{k}}) N^i_{\bar{k}\bar{j}} + (\partial_{\bar{j}} v^{\bar{k}} - \mu^k_{\bar{j}} \partial_k v^{\bar{k}}) N^i_{\bar{s}\bar{k}} \\
+ v^k \partial_k N^i_{\bar{s}\bar{j}} + v^{\bar{k}} \partial_{\bar{k}} N^i_{\bar{s}\bar{j}}
\end{gathered}
\tag{36}
$$

The transformation laws (30), (36) generate the following covariant behavior of the beta-function (24)

$$
B_{i\bar{j}} \to B_{i\bar{j}} + v^k \partial_k B_{i\bar{j}} + v^{\bar{k}} \partial_{\bar{k}} B_{i\bar{j}} + B_{i\bar{k}} (\partial_{\bar{j}} - \mu^k_{\bar{j}} \partial_k) v^{\bar{k}} + B_{l\bar{j}} (\partial_i - \bar{\mu}^{\bar{k}}_i \partial_{\bar{k}}) v^l \tag{37}
$$

which, according to consistency requirements, exactly coincide with the transformation law for the $b$-field (33). It is necessary to point out, that formulas (37) and (33) coincide exactly, only when the nontrivial transformation law of (17) is taken into account. Also, multiplying by the matrices $M^i_j$ and $\bar{M}^{\bar{i}}_{\bar{j}}$ from (17), one can rewrite e.g. (32), (36)

$$
\begin{gathered}
\widehat{g}^{i\bar{j}} \to \widehat{g}^{i\bar{j}} + v^k \partial_k \widehat{g}^{i\bar{j}} + v^{\bar{k}} \partial_{\bar{k}} \widehat{g}^{i\bar{j}} - \mathcal{D}_k v^i \widehat{g}^{k\bar{j}} - \mathcal{D}_{\bar{k}} v^{\bar{j}} \widehat{g}^{i\bar{k}} \\
\widehat{N}^i_{\bar{s}\bar{j}} \to \widehat{N}^i_{\bar{s}\bar{j}} - \mathcal{D}_k v^i \widehat{N}^k_{\bar{s}\bar{j}} + \mathcal{D}_{\bar{s}} v^{\bar{k}} \widehat{N}^i_{\bar{k}\bar{j}} + \mathcal{D}_{\bar{j}} v^{\bar{k}} \widehat{N}^i_{\bar{j}\bar{k}} + v^k \partial_k \widehat{N}^i_{\bar{s}\bar{j}} + v^{\bar{k}} \partial_{\bar{k}} \widehat{N}^i_{\bar{s}\bar{j}}
\end{gathered}
\tag{38}
$$

for $\widehat{g}^{i\bar{j}} = M^i_k M^{\bar{j}}_{\bar{k}} g^{k\bar{k}}$ and $\widehat{N}^i_{\bar{s}\bar{j}} = M^i_k N^k_{\bar{s}\bar{j}}$ purely in terms of the long derivatives (35). Not quite canonical form of the field's transformations found in this section can be explained by considering perturbed first-order theory as a particular gauge of more generic form for such action, written in terms of the vielbein background fields.

## 4 The alternative first-order action

The perturbed action (11) can be also considered as a particular case of more general non-linear theory with the action

$$
L = p_a e^a_\mu(X) \bar{\partial} X^\mu + c.c + \ldots \tag{39}
$$

where $a, b = 1, \ldots, D/2$ and $\mu, \nu = 1, \ldots, D$, and the external fields appear now in the form of veilbein, or the one-forms $e = e_\mu dX^\mu$ and $\bar{e} = \bar{e}_\mu dX^\mu$ with values in the holomorphic and antiholomorphic subspaces of the complexified tangent bundle. The covariance of the action (39) is transparent, while the action (11) can be obtained from (39) imposing the gauge $e^a_i = \delta^a_i$, $e^a_{\bar{j}} = \mu^a_{\bar{j}}$. We also define $(A = \{a, \bar{a}\})$

$$
\begin{aligned}
e^\mu_A e^B_\mu &= \delta^B_A, \quad A, B = 1, \ldots, D, \quad \text{or} \\
e^\mu_a e^b_\mu &= \delta^b_a, \quad a, b = 1, \ldots, D/2 \\
e^\mu_{\bar{a}} e^{\bar{b}}_\mu &= \delta^{\bar{b}}_{\bar{a}}, \quad \bar{a}, \bar{b} = 1, \ldots, D/2
\end{aligned}
\tag{40}
$$

The fields $p_a$ and $p_{\bar{a}}$ are still $(1,0)$ and $(0,1)$ world-sheet forms with values in the pullbacks of the holomorphic and antiholomorphic pieces of the cotangent bundle, equipped with the unitary structure.

Decomposing again $X \to X + x$ into classical fields and quantum fluctuations, one gets for (39)

$$
L = \ldots + p_a e^a_\mu(X) \bar{\partial} x^\mu + p_a \partial_\nu e^a_\mu(X) \partial X^\mu x^\nu + c.c + \ldots \tag{41}
$$

which can be further rewritten introducing $x^\mu = e^\mu_a(X) Y^a + e^\mu_{\bar{a}}(X) Y^{\bar{a}}$ as

$$
L = \ldots + p_a \bar{\partial} Y^a + p_a \mathcal{W}^a_b Y^b + p_a \mathcal{U}^a_{\bar{b}} \bar{Y}^{\bar{b}} + c.c + \ldots \tag{42}
$$

with

$$
\begin{gathered}
\mathcal{U}^a_{\bar{b}} = (de)^a_{\mu\nu} e^\mu_{\bar{b}} \bar{\partial} X^\nu, \quad \mathcal{W}^a_b = (de)^a_{\mu\nu} e^\mu_b \bar{\partial} X^\nu \\
(de)^a_{\mu\nu} = \partial_{[\mu} e^a_{\nu]}
\end{gathered}
\tag{43}
$$

Following the same argumentation, as in sect. 2, one gets that the logarithmic divergence comes from the only one-loop diagram (depicted at fig. 1, with $U$'s being replaced by $\mathcal{U}$'s), and has the form

$$
B \sim \mathcal{U}^a_{\bar{b}} \bar{\mathcal{U}}^{\bar{b}}_a = \mathcal{N}^a_{\bar{c}\bar{b}} \bar{\mathcal{N}}^{\bar{b}}_{ca} e^c_\mu \bar{e}^{\bar{c}}_\nu \partial X^\mu \bar{\partial} X^\nu \tag{44}
$$

which is another form of the result (24), and we have introduced in (44) the tangent-space components $\mathcal{N}$ of the Nijenhuis tensor.

To understand the last equality in (44), consider connection in the complexified tangent bundle with torsion

$$
de^a = (a_\mu)^a_c dX^\mu \wedge e^c + (b_\mu)^a_{\bar{c}} dX^\mu \wedge \bar{e}^{\bar{c}} \tag{45}
$$

The Nijenhuis tensor comes from the $b$-part of (45) to be defined as

$$
[\bar{e}_{\bar{b}}, \bar{e}_{\bar{c}}] = -\mathcal{N}^a_{\bar{b}\bar{c}} e_a + \mathsf{f}^{\bar{a}}_{\bar{b}\bar{c}} \bar{e}_{\bar{a}} \tag{46}
$$

where $e_a$ and $\bar{e}_{\bar{b}}$ are considered as vector fields and equation (46) can be considered as integrability condition of the system of equations on holomorphic functions

$$
\bar{e}_{\bar{b}} f = \bar{e}^\mu_{\bar{b}} \frac{\partial}{\partial X^\mu} f = 0, \quad \bar{b} = 1, \ldots, D/2 \tag{47}
$$

On the equations of motion $e^a_\mu \bar{\partial} X^\mu = 0$ for the theory (39) one can write

$$
\mathcal{U}^a_{\bar{b}} = (de)^a_{\mu\nu} e^\mu_{\bar{b}} \bar{\partial} X^\nu = (de)^a_{\mu\nu} e^\mu_{\bar{b}} \bar{e}^\nu_{\bar{c}} \bar{e}^{\bar{c}}_\lambda \bar{\partial} X^\lambda \tag{48}
$$

This gives rise immediately to (44) since

$$\bar{e}^{\mu}_{\bar{a}}\partial_{\mu}\bar{e}^{\nu}_{\bar{b}} = -\bar{e}^{\mu}_{\bar{a}}\left(\bar{e}^{\nu}_{\bar{c}}\partial_{\mu}\bar{e}^{\bar{c}}_{\lambda}\bar{e}^{\lambda}_{\bar{b}} + e^{\nu}_{c}\partial_{\mu}e^{c}_{\lambda}\bar{e}^{\lambda}_{\bar{b}}\right) \tag{49}$$

The first term in the r.h.s. is inessential for the Nijenhuis tensor in (46), while the second gives

$$(de)^{a}_{\mu\nu}e^{\mu}_{\bar{b}}\bar{e}^{\nu}_{\bar{c}} = \partial_{[\mu}e^{a}_{\nu]}e^{\mu}_{\bar{b}}\bar{e}^{\nu}_{\bar{c}} = -\bar{e}^{\nu}_{[\bar{b}}\partial_{\nu}\bar{e}^{\mu}_{\bar{c}]}e^{a}_{\mu} = \mathcal{N}^{a}_{\bar{c}\bar{b}} \tag{50}$$

which completes the proof of (44). The bets function (44) in the first-order theory (39) is again expressed in terms of the Nijenhuis tensor and therefore vanishes on the Kodaira-Spencer equations.

Let us finally present explicit relations between the vielbein language and original first-order theory. Solving (40) for the inverse vielbein at the point, where $e^{a}_{j} = \delta^{a}_{j}$ and $e^{a}_{\bar{j}} = \mu^{a}_{\bar{j}}$, one gets

$$e^{i}_{a} = M^{i}_{a}, \quad e^{i}_{\bar{b}} = -M^{i}_{k}\mu^{k}_{\bar{b}} = -M^{\bar{k}}_{\bar{b}}\mu^{i}_{\bar{k}} \tag{51}$$

and the rest can be obtained by complex conjugation. Hence,

$$\bar{e}_{\bar{b}} = \bar{M}^{\bar{k}}_{\bar{b}}\mathcal{D}_{\bar{k}} \tag{52}$$

where the long derivatives (35) give rise to the Nijenhuis tensor by their commutator $[\mathcal{D}_{\bar{i}},\mathcal{D}_{\bar{j}}] = -N^{k}_{\bar{i}\bar{j}}\partial_{k}$. Therefore

$$\begin{aligned}[\bar{e}_{\bar{b}},\bar{e}_{\bar{c}}] = [\bar{M}^{\bar{k}}_{\bar{b}}\mathcal{D}_{\bar{k}},\bar{M}^{\bar{l}}_{\bar{c}}\mathcal{D}_{\bar{l}}] = -\bar{M}^{\bar{k}}_{\bar{b}}\bar{M}^{\bar{l}}_{\bar{c}}N^{a}_{\bar{k}\bar{l}}\partial_{a} + \bar{M}^{\bar{k}}_{[\bar{b}}\mathcal{D}_{\bar{k}}\bar{M}^{\bar{l}}_{\bar{c}]}\mathcal{D}_{\bar{l}} = \\ = -\bar{M}^{\bar{k}}_{\bar{b}}\bar{M}^{\bar{l}}_{\bar{c}}N^{a}_{\bar{k}\bar{l}}e_{a} + (\bar{M}^{\bar{k}}_{[\bar{b}}\mathcal{D}_{\bar{k}}\bar{M}^{\bar{l}}_{\bar{c}]} - \bar{M}^{\bar{k}}_{\bar{b}}\bar{M}^{\bar{s}}_{\bar{c}}N^{a}_{\bar{k}\bar{s}}M^{\bar{l}}_{\bar{d}}\bar{\mu}^{\bar{d}}_{a})\mathcal{D}_{\bar{l}}\end{aligned} \tag{53}$$

since $\partial_{i} = M^{k}_{i}\mathcal{D}_{k} + M^{\bar{k}}_{\bar{l}}\bar{\mu}^{\bar{l}}_{i}\mathcal{D}_{\bar{k}}$. Comparing (53) with (46), one finds

$$\bar{M}^{\bar{k}}_{\bar{b}}\bar{M}^{\bar{l}}_{\bar{c}}N^{a}_{\bar{k}\bar{l}} = \mathcal{N}^{a}_{\bar{b}\bar{c}} \tag{54}$$

The symmetries in vielbein formalism are more transparent. Consider the perturbed action:

$$L[e,g,b] = p_{a}e^{a}_{\mu}\bar{\partial}X^{\mu} + c.c. + g^{a\bar{a}}p_{a}p_{\bar{a}} + b_{\mu\nu}\partial X^{\mu}\bar{\partial}X^{\nu} \tag{55}$$

Under the general co-ordinate transformation

$$X^{\mu} \to X^{\mu} - v^{\mu}(X) \tag{56}$$

which is an equivalent of (28), this action transforms into:

$$\begin{aligned}\delta L[e,g,b] = \left[(\delta p_{a})e^{a}_{\mu} + p_{a}(\delta e^{a}_{\mu} - v^{\nu}\partial_{\nu}e^{a}_{\mu} - e^{a}_{\nu}\partial_{\mu}v^{\nu})\right]\bar{\partial}X^{\mu} + c.c. + \delta(g^{a\bar{a}}p_{a}p_{\bar{a}}) - \\ -v^{\mu}\partial_{\mu}g^{a\bar{a}}p_{a}p_{\bar{a}} + [\delta b_{\mu\nu} - v^{\rho}\partial_{\rho}b_{\mu\nu} - b_{\rho\nu}\partial_{\mu}v^{\rho} - b_{\mu\rho}\partial_{\nu}v^{\rho}]\,\partial X^{\mu}\bar{\partial}X^{\nu}\end{aligned} \tag{57}$$

Thus, it is invariant, in particular, under the following transformations

$$\begin{gathered}\delta p_{a} = 0, \ \ \delta g^{a\bar{a}} = v^{\mu}\partial_{\mu}g^{a\bar{a}} \\ \delta b_{\mu\nu} = v^{\rho}\partial_{\rho}b_{\mu\nu} + b_{\rho\nu}\partial_{\mu}v^{\rho} + b_{\mu\rho}\partial_{\nu}v^{\rho} \\ \delta e^{a}_{\mu} = v^{\nu}\partial_{\nu}e^{a}_{\mu} + e^{a}_{\nu}\partial_{\mu}v^{\nu}\end{gathered} \tag{58}$$

and the $\mathcal{N}$-components of the Nijenhuis tensor simply transform as

$$\delta\mathcal{N}^{a}_{\bar{b}\bar{c}} = v^{\rho}\partial_{\rho}\mathcal{N}^{a}_{\bar{b}\bar{c}} \tag{59}$$

# 5 Discussion

We have considered in this paper the first-order theory, which hypothetically corresponds to a string theory in singular backgrounds, when expanding around the bare action (1). This theory depends only on the (local) choice of target-space complex structure and we have studied this dependence by perturbing the bare action by the Beltrami vertex operator (6).

The background effective action, which arises after dividing world-sheet fields into the slow and fast variables and the one-loop integration over the latter contains the beta-function of the operator (5), vanishing on the Kodaira-Spencer equations (10) for the target-space Beltrami differentials (4). This result comes after an almost trivial computation of the Gaussian integral, which however clarifies several delicate issues, and requires certain field redefinition in the space of fast variables, corresponding to change of complex polarization in target-space for a nontrivial background. The computed beta-function is proportional to *squared* Kodaira-Spencer equations (24), where the conjugated components of the Nijenhuis tensor (10) are contracted by certain matrices, depending on the components of Zamolodchikov metric is the space of primary operators or background fields for the first-order string theory. Reformulating this result in the form (44), one finds that this extra metric in the space of target-space fields can be rewritten in the form of inverse vielbein fields (40). We have also discussed briefly the consistency of this result with the exact symmetries of the perturbed theory.

This result can be also reproduced from direct computation of the correlation functions in conformal theory (1). The "co-ordinate" beta-functions arise in such approach as particular integrals over the moduli spaces of punctured world sheets of the first-order string theory, partially this approach has been discussed in [16]. The detailed analysis of this approach will be published in the second part of this paper [15], and here finally we will only sketch the idea.

To study the co-ordinate approach to the beta-functions consider, for example, the perturbed one-point correlation function of the "probe operator" (3)

$$\langle O_g(x)\rangle_t = \langle O_g(x)\exp(t\int_\Sigma \Phi)\rangle = \sum_{n\geq 0}\frac{t^n}{n!}\int_\Sigma d^2z_1\dots\int_\Sigma d^2z_n\langle O_g(x)\Phi(z_1)\dots\Phi(z_n)\rangle \tag{60}$$

where averaging in the r.h.s. is understood in the sense of path integral with the free action (1). The calculation of the r.h.s. of (60) includes the integration of the multipoint correlators

$$\langle O_g(x)\Phi(z_1)\dots\Phi(z_n)\rangle \tag{61}$$

over the regularized domain $\Sigma^{\otimes n}$, e.g.

$$\begin{gathered}|z_i - x| > \epsilon, \qquad |z_i - z_j| > \epsilon \\ \forall i,j = 1,\dots,n\end{gathered} \tag{62}$$

In order to get a hint of what should we expect from such computation, consider the first nontrivial order, namely the correlator (61) for $n = 2$

$$\langle O_g(x)\Phi(y)\Phi(z)\rangle = \langle O_g(x)O_\mu(y)O_{\bar\mu}(z)\rangle + \langle O_g(x)O_{\bar\mu}(y)O_\mu(z)\rangle \tag{63}$$

The direct computation of the free field correlator in the r.h.s. of (63) gives rise to the result

$$\frac{1}{2}\langle O_g(x)\int_\Sigma \Phi(y)\int_\Sigma \Phi(z)\rangle \approx \frac{g^{i\bar{j}}B^{(2)}_{i\bar{j}}}{|x|^4}\log\frac{R^2}{\epsilon^2}\int\limits_{|y|<R}\frac{d^2y}{\pi} \tag{64}$$

The coefficient at the logarithmic singularity (64) is proportional to the function

$$g^{i\bar{j}}B^{(2)}_{i\bar{j}} = g^{k\bar{k}}\partial_{[i}\bar{\mu}^{\bar{j}}_{k]}\partial_{[\bar{k}}\mu^{i}_{\bar{j}]} \tag{65}$$

Strictly speaking, instead of $g^{k\bar{k}}\partial_{[i}\bar{\mu}^{\bar{j}}_{k]}\partial_{[\bar{k}}\mu^{i}_{\bar{j}]}$ one should write a target-space integral

$$\int d^DX^{(0)}g^{k\bar{k}}(X^{(0)})\partial_{[i}\bar{\mu}^{\bar{j}}_{k]}(X^{(0)})\partial_{[\bar{k}}\mu^{i}_{\bar{j}]}(X^{(0)}) \tag{66}$$

over the zero modes $X^{(0)}$ of the $X$-fields, and consider the compact target, or the target-space fields being coefficients functions of the operators (3) and (4) vanishing at the space-time "infinity", what allows integration by parts in (66); together with the transversality constraints (7) this bring us to (63). The computation of the 3-point function (63) is almost equivalent to the calculation of the operator product expansion of two operators $\Phi$

$$\begin{gathered}\Phi(z)\Phi(0) = \frac{2\bar{\mu}^{\bar{j}}_{i}\mu^{i}_{\bar{j}}}{|z|^4} + \frac{\partial_k\left(\bar{\mu}^{\bar{j}}_{i}\mu^{i}_{\bar{j}}\right)\partial X^k}{z\bar{z}^2} + \frac{\partial_{\bar{k}}\left(\bar{\mu}^{\bar{j}}_{i}\mu^{i}_{\bar{j}}\right)\bar{\partial}X^{\bar{k}}}{z^2\bar{z}} + \frac{2\tilde{B}^{(2)}_{i\bar{j}}\partial X^i\bar{\partial}X^{\bar{j}}}{|z|^2} + \dots\\ \tilde{B}^{(2)}_{i\bar{j}} = B^{(2)}_{i\bar{j}} + \tfrac{1}{2}\left(\partial_i\mathsf{w}_{\bar{j}} + \partial_{\bar{j}}\mathsf{w}_i\right)\\ \mathsf{w}_{\bar{j}} = \partial_{[\bar{j}}\mu^{k}_{\bar{k}]}\bar{\mu}^{\bar{k}}_{k},\quad \mathsf{w}_i = \partial_{[i}\bar{\mu}^{\bar{k}}_{k]}\mu^{k}_{\bar{k}}\end{gathered} \tag{67}$$

with its further projection onto the operator $O_g$, being in this sense equivalent to the computation of the quadratic contribution into the beta-function of the operator $O_b$ (see e.g. [1, 9]).

We see therefore, that computation of the singularity of the 3-point function (63) reproduces the quadratic in $\mu$-fields piece of the beta-function (24). It is quite instructive to discuss therefore, how the next terms $B^{(3)}_{i\bar{j}}$ arise from the four-point contribution. This is already not very trivial computation, requiring special care, when considering the integrals over the world-sheet moduli space [15].

It is important, that nonlinear equations for the background fields arise in this approach from the correlation functions with *different* number of operators (the so called polyvertex structures, already discussed in this context in [5, 17]), and contain integrals over the moduli spaces of punctured world sheets with different numbers of punctures. This is close to already discussed in similar context structures of the string field theory (see e.g. [18, 19]). Generally we believe that such approach should lead to solvable nonlinear equations for the "co-ordinate" beta-functions and we are going to return to these issues elsewhere.

## Acknowledgements

We are grateful to G. Arutyunov, M. Kontsevich, N. Nekrasov, A. Rosly, A. Smilga and A. Tseytlin for important discussions. OG also thanks V. Shadura and N. Iorgov for permanent encouragement and support. AM thanks the IHES in Bures-sur-Yvette, the MPIM in

Bonn and the Galileo Galilei Institute in Florence, where essential parts of this work have been done.
